

# Moving on to Factor Seven -

#### **Using Genetics to Breed Better Racing Pigeons**

2016 Convention American Racing Pigeon Union Ontario, California

> Dave Shewmaker Shewmaker Genetics (916) 662-5339 www.shewmaker.com dave@shewmaker.com

Dave Shewmaker on Facebook FB Group: Racing Pigeon Forum

#### **Overview**

- My Biases
- Some Background Information
- The Rule of Seven
- Moving on to Factor Seven
- Basic Genetics
- The Bell Curve
- The Progress Equation
- New Tools (AI, LDHA, DRD4)
- Genes Affecting Racing Ability
- A Road Map for Genetic Improvement
- Closing Thoughts

## My Biases

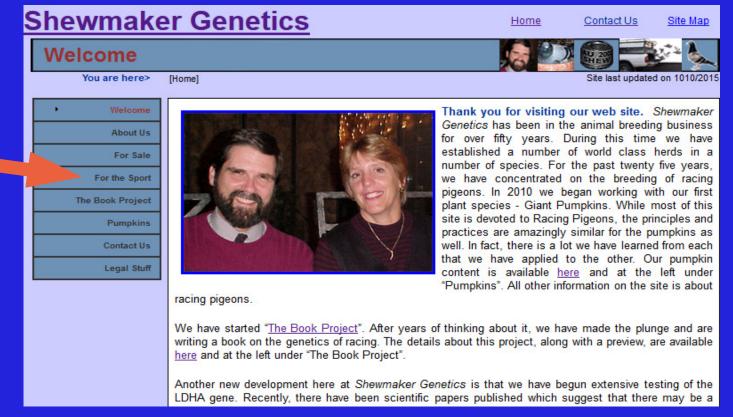

- My degree is in genetics.
- I have been an animal breeder and consultant for over 50 years working with dozens of species including swine, cattle, sheep, horses, rabbits and racing pigeons.
- So I have strong opinions based on these two frames of reference.
- I am here just to share and not to win converts you can and should do it any way you want.
- Pigeon Racing is a hobby keep it relevant to what you enjoy.

### **Some Background Information**

 My web site (www.shewmaker.com) has some additional information that you may find helpful in sorting out some of the ideas we are going to talk about today (Under the "For the Sport" tab).

## Some Background Information

- There is also a pretty useful discussion group on Facebook that I host where you can ask questions.
- It is called "Racing Pigeon Forum".

Helpful posts about pigeon racing. Please do not post anything about any topics not related to pigeon racing. Disagreements are fine, but please no rude behavior. Looking to share and find information not commonly seen elsewhere.

You are welcome to join.

#### The Rule of Seven \*

- There are seven factors which determine how well you and your birds will perform in pigeon racing.
- One is beyond your control.
- Five are so well perfected within the sport that they have become essentially pass/fail.
   You either cover them competently or you are virtually eliminated from the winning positions even before the race starts.
- One has almost no limit to its potential and is largely unrealized by most fanciers.

#### The Rule of Seven

- 1)Beyond our control <u>luck</u>. Good luck, bad luck, hawks, wires, wind direction, basket position on the truck, bad weather along the course, good weather along the course when we entered a tough weather bird, and on and on and on. It affects us all and so we should just get over it and move on to what we can control.
- 2)Condition (pass/fail)
- 3)Training (pass/fail)
- 4)Fuel (pass/fail)
- 5) Motivation (pass/fail)

#### The Rule of Seven

6)Health (pass/fail though too many flyers are still failing on this one. We could have a week of seminars just on this topic alone.)

## 7) Genetics

When Louis Van Loon was asked "What methods do you use to get those kind of results?" he looked sternly at the gentleman and said, "Remember this, there is only one thing that is important – good pigeons, nothing else."

### Its Time to Move to Factor Seven

- Gregor Mendel's work was published in 1865 (that was 150 years ago!)
- Consider some of the other key discoveries or inventions of that era and their impact on us today:
  - 1861 Louis Pasteur Germ Theory
  - 1873 James Maxwell Theory of Electromagnetism
  - 1886 Benz & Daimler First gasoline automobiles
  - 1898 Marie Curie Polonium and Radium
  - 1905 Albert Einstein Theory of Special Relativity

### Its Time to Move to Factor Seven

- The science of genetics has made enormous progress since then:
  - 1952 Hershey/Chase DNA is likely the genetic material
  - 1953 Watson & Crick Structure of DNA
  - 1978 Genetech Genetically engineered human insulin
  - 1986 First use of DNA in court proceedings
  - 2003 Complete map of the human genome
  - 2015 FDA approval of genetically modified virus for targeted cancer treatment

#### Its Time to Move to Factor Seven

- Yet many racing pigeon breeders today still struggle applying even the basic work of Mendel.
  - Some on the forums even question if Mendel's work applies to pigeon racing.
- Yes, it can be complex, but it doesn't have to be.
  - You don't have to know how to build a watch, to be able to use one to tell time.

## **Moving to Factor Seven**

## The three objectives of this seminar are to

- 1. Implore each of you to move on to that seventh factor of racing success, genetics
- 2. Provide you with a high level road map for making genetic improvement
- 3. Introduce you to an exciting new development, DNA testing for performance related genes

- Pigeons have 40 pairs of unique chromosomes for a total of 80 chromosomes.
- On the chromosomes, reside genes. You can think of them as being like beads on a string. The individual beads are the genes and a particular string of these genes is a chromosome.
- The genes are the precise blueprint for every <u>trait</u> of an individual.
- These traits range from what we can easily observe (like the color of the eye) to less discrete and intangible things like mental attitude.

- During fertilization, each parent contributes one chromosome of each of the 40 pairs.
  - One of these pairs (the Sex Chromosomes W and Z) is unique in that the W chromosome contains no genes. Cocks are ZZ and hens are WZ. So for a small number of genes (1/40th or 2.5%) hens did not receive a contribution from their mother. These are referred to as "sex linked traits".
  - I do not subscribe to the theory that the hen contributes more significantly than the cock due to mitochondrial DNA (e.g. there is evidence of paternal contribution and the majority of mitochondrial processes are coded for by nuclear DNA). In the absence of data to support this claim, you should avoid placing any disproportionate value on the dam.
  - Due to cross over during meiosis, grandparents DO NOT equally contribute 25%).

- Each trait is coded for by one or more pairs of genes.
- A given gene resides on a specific location of a specific chromosome. This location is known as a locus (the plural form is loci.)
- While an individual will have exactly two genes for each locus (one coming from each parent), there are multiple versions of that gene within the gene pool (the breeding population). Each different version is known as an <u>allele</u>.

- For example, the trait "feather color pattern" has at least four alleles (Dark Check, Check, Bar and Barless) for which a given bird will have at most two.
- All four of these <u>phenotypes</u> are coded for by a single pair of genes on one of the chromosome pairs. If the parents both contributed the "Bar" gene (+) the resulting pigeon will have a Bar color pattern. However, if both parents contributed the "Check" gene, the resulting pigeon will have a Check color pattern.
- When genes for a given pair are of the same type (allele) the pair is said to be <u>homozygous</u>. If the pair consists of two different alleles the pair is said to be <u>heterozygous</u>.

- When heterozygous, there are two possible ways the trait might be expressed (though it will always be expressed the same way for a particular gene pair).
  - Complete dominance is when one allele determines the phenotype (dominant) and the other allele is completely masked (recessive) as if it didn't even exist. What we see is the phenotype and what is actually there in the genes of the cells is known as the genotype.
  - <u>Incomplete dominance</u> is when the gene expression is intermediate in the heterozygous state (the gene locus for Grizzle is one example).

Lets look at our example of feather color pattern.
 There are four possible alleles.

	Allele Symbol	Expression
c <sup>T</sup>	(known as the T-pattern check)	Dark Check
С	(Uppercase)	Check
+		Bar
<u>C</u>	(lowercase)	Barless

- $C^T > C > + > \underline{c}$  or in other words -
  - Dark Check is dominant over Check, Bar and Barless
  - Check is dominant over Bar and Barless
  - Bar is dominant over Barless

These are all the possible ways the alleles can be paired up.

Ge	not	ype

$$C^T C^T$$

$$C^T$$

$$\mathsf{C}^\mathsf{T}$$
 +

$$C^{T}$$

#### Phenotype

**Dark Check** 

Dark Check

Dark Check

Dark Check

Check

Check

Check

Bar

Bar

Barless

 This is why you can't get a Check or a Dark Check when you mate two Bars together. If you see such a situation in a pedigree you might suspect there is a mistake somewhere (be careful though because people will sometimes call a light Check a Bar).

	Sire	+	+
Dam			
+		+ +	+ +
+		+ +	+ +

Example of a Bar cock with the ++ genotype mated to a Bar hen also with the ++ genotype. The mating will produce 100% Bars.

But you can get Bars from the mating of two Checks.

Example of a Check cock with the C+ genotype mated to a Check hen also with the C+ genotype. The mating should produce 75% Checks and 25% Bars.

 Though some Checks when mated will not ever produce a single Barred offspring.

Example of a Check cock with the CC genotype mated to a Check hen also with the CC genotype. The mating will produce 100% Checks.

## Our Concern Is With The Big Picture

- Genetics though is <u>much</u> more complicated than what we have explained so far for a simple pair of genes.
- This leads many people to get lost in the minutia of DNA, genes, mutations and such.
- It is much more important to understand the big picture. Remember, it is fine to understand how a watch works, but most people are better served by simply knowing how to tell time.
- In general, don't think in terms of individual genes, individual chromosomes or even individual birds. Everything should be approached from the point of view of the <u>population</u> of racing pigeons specifically those in your loft and those in the rest of the sport.

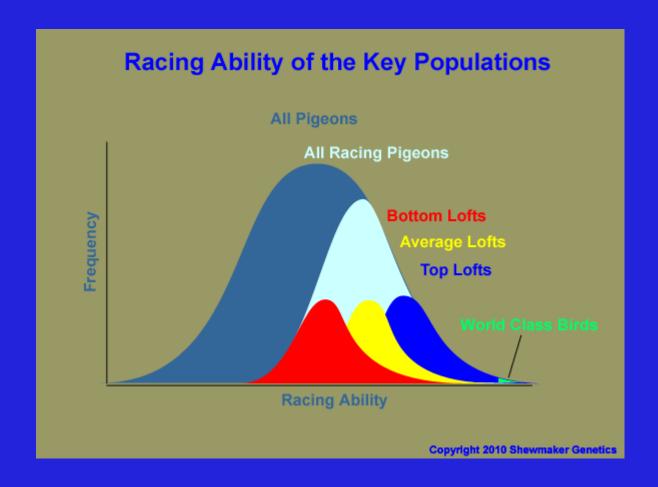

### **Understand Its a Bell Curve**

- For many traits, genetic expression is actually determined not by the action of a single pair of genes but multiple pairs two, three, dozens and perhaps even hundreds in the case of those non-discrete traits like "height" or "body weight" or in our case "racing ability".
- If you do the math and graph outcomes of various matings using many genes, instead of a box where 75% are Checks and 25% are Blues (as on Slide 21), we get a distribution that is known as a bell curve.
- The next five slides are the most important of the whole seminar.

#### Understand Its a Bell Curve \*

 Notice that the "Bottom Lofts" and most of the "Average Lofts" may not even have the necessary genes in their pool to breed world class birds.

### **Understand Its a Bell Curve**

 But also notice that in the "Top Lofts", few of the birds are "World Class" and many are on a par with the "Low" and "Average" lofts.

### **Understand Its a Bell Curve**

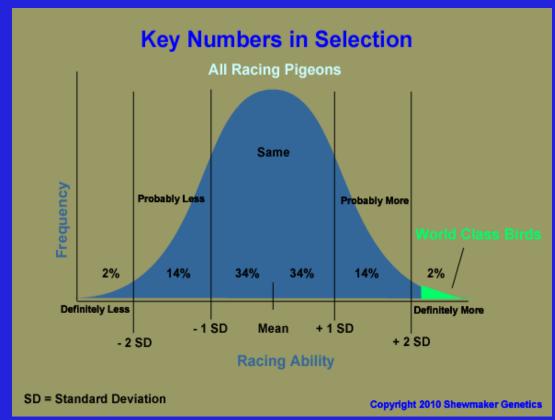

- Here is the hard cold fact most of our pigeons are not genetically up to our assumptions and expectations.
- <u>IF</u> you have a "Top Loft" complete with a few "World Class" pigeons, you <u>MIGHT</u> produce 1 in 10 birds which should be kept to breed the next generation.
- If you are in the "Average Loft" category it is probably closer to 1 in 100 and in the "Bottom Lofts" it is closer to 1 in 1000 or maybe even 1 in 10,000.

### Understand Its a Bell Curve \*

 If you aren't selecting at least the top 16% <u>you probably</u> aren't selecting at all.

 If you really want to make progress you need to be selecting at least the top 2%.

### The Progress Equation ★

- Your ability to make genetic progress and the speed at which
  you make this progress is <u>absolutely</u> related to these three
  factors (*memorize this slide*!):
  - The <u>accuracy</u> of your selection
    - So if you think toe color is related to superior racing and this is what you select for, you are probably not really doing any selection at all with respect to racing ability. In my view the most accurate selection criteria (by a wide wide margin) is race results to the same loft. Nothing else comes close.
  - The <u>intensity</u> of your selection
    - Selecting from the top 16% is far less intense than selection from the top 2% which in turn is far less intense than selecting from the top 1%
  - The <u>time</u> interval over which you do the selection
    - One season is not enough, but two or three will surprise you.
       Changing to a new fad (or a new family) every few years will doom any real progress.

#### **New Tools – Artificial Insemination**

Artificial Insemination is an incredibly powerful tool for the proliferation of the elite birds.

- Fresh semen can typically be collected three times a week, year round.
  - One collection can typically inseminate six to ten hens when used fresh and about three when frozen.
  - Once frozen the semen can be stored indefinitely (literally for decades).

#### **New Tools – Artificial Insemination**

#### Artificial Insemination Advantages (continued).

- Semen can be collected and frozen from race team cocks during and between race seasons. This is huge.
  - It allows us to preserve the genetics of the elite birds while continuing to race them and gather data. In the past we have often had to chose between stocking and racing which resulted in some birds being either
    - stocked too early before their true racing value was accurately established, or
    - sent to one too many races wherein a valuable bird was lost.

### New Tools – DNA Testing ★

The fantastic advances in DNA technology are now available to the sport of pigeon racing!

- DNA Profiling allows us to record the genetic "fingerprint" of a pigeon. This can be very useful later for a variety of verification scenarios.
- Verification of Parentage. While a 100% verification is not possible, the use of at least 16 carefully chosen markers will allow parentage to be verified to a very reasonable degree. www.animalgenetics.com performs this service.
- Sex determination.
- We can now determine the actual genotypes of birds for two genes that have been shown to influence race performance. More are undoubtedly coming.

Recent research has shown that the LDHA gene may play a very important role in racing performance of pigeons.

I believe this is a very important topic, but a strong word of caution is in order.

- First and foremost, the LDHA gene is but one of many that contribute to racing ability. Anyone who jumps off the cliff at this point and assumes that LDHA is the secret and exclusive "silver bullet" which will ensure immediate racing success, is almost certainly wrong and will likely end up being very disappointed.
- By the same token, anyone who dismisses these research results as techno babble and irrelevant to real world racing is also very likely wrong and might be missing a significant opportunity to move their gene pool dramatically forward.

#### What is it?

- LDH stands for Lactate Dehydrogenase, a group of enzymes that are involved in the conversion of lactate to pyruvate (and vise versa).
- LDH is found in the cells of virtually every living organism (plants, animals and even single cell organisms known as prokaryotes).
- In mammals and birds, there are three different forms of this enzyme that are largely found in specific cell types, reflecting the different functional requirements of those cells. Each type is coded for by a different gene.
- The type A form of LDH is found largely in muscle cells and is coded for by the LDHA gene

#### What is it?

- When sufficient oxygen is present, muscle cells produce energy from a metabolic process known as aerobic respiration.
- When the exercise is sufficiently intense or prolonged such that there is an oxygen deficit, muscle cells use an alternative anaerobic process that produces lactate (lactic acid). Note that pigeons use a metabolic pathway for energy that uses fat and does not produce lactate after the first hour of flight.
- For many years, it was erroneously thought that muscle fatigue during strenuous exercise was due to a build up of lactic acid. We now know that there are several factors that contribute to fatigue, but how a cell utilizes and/or regulates lactate levels can influence race performance.

#### What did the research find?

- In 2002, two different alleles were found in pigeons for the LDHA gene, A and B. This means the possible genotypes for LDHA in pigeons are BB, AB and AA.
- In 2006, DNA testing was used to determine the frequencies of the A and the B alleles in four groups of pigeons:
  - The group of fancy pigeons (non racing breeds) had an A allele frequency of 0.6%.
  - A control group of race pigeons (not screened for racing results) had an A allele frequency of 6.5%.
  - A group of race pigeons from throughout Poland (specifically screened for "top" racing results) had an A allele frequency of 20.3%.
  - A group of race pigeons from throughout China and Taiwan (specifically screened for "top" racing results) had an A allele frequency of 21.9%.

#### What did the research find?

- In 2014, another study was done which again demonstrated a correlation between the frequency of the A allele and race performance.
- This 2014 study also raised the possibility that the influence of the AA genotype may exceed that of the AB genotype in races under 250 miles and that the A allele may be less important in the distance races of more than 311 miles.
- At this point there are many unanswered questions.
   Much additional research needs to be done.

#### What does this all mean?

- In selecting for race performance, pigeon breeders have indirectly been selecting for the A allele of the LDHA gene (along with others of course that have not yet been identified). This is shown by the ten fold increase in the frequency of the A allele of the racing pigeon control group over that of the fancy pigeons in the 2006 study.
- The three fold increase in the frequency of the A allele of "elite" racing pigeons over the racing pigeon control group further supports the notion that the A allele enhances race performance.

#### What does this all mean?

- Today, the LDHA genotype of any pigeon can be determined by a DNA test. In the US, the test can be performed for \$20 with the submission of a single secondary feather. ( www.genecheck.com )
- Another good U.S. lab is www.animalgenetics.com and in Europe www.pigen.be is excellent.
- It is now possible for the astute breeder to "fix" the A allele of the LDHA gene in their breeding flock, making its frequency 100%. They are then free to focus on additional improvement through the selection of other key genes, knowing the A allele will always be there in any birds they produce.

Don't forget – this is an important gene, but it is not the whole story. There are many outstanding birds (both racers and breeders) who are BB.

- Don't make the mistake of culling birds just because they do not carry the A allele.
- Think instead in terms of adding the A allele to improve existing gene pools and then increasing its frequency.

[This is where the seminar ended on this topic last year]

### **New Tools – DNA Testing**

In 2013 I bred an incredible bird. His Contemporary Group Test record was unlike any of the thousands of birds I have tested. No other bird has had a record that was even close. He was an off the chart freak!

- His band was 3079-AU-13-SHEW and I named him "The Freak" (sorry Frank McLaughlin, I didn't know at the time you had one with the same name).
- Later when I started testing my birds for the LDHA gene, I assumed he would probably be at least AB and maybe even AA.
- Well he wasn't. He was just a BB.

### **New Tools – DNA Testing**

In 2013 I bred an incredible bird... He was an off the chart freak!

- There is this natural tendency when doing gene testing to be disappointed when the results come back without the hoped for (or expected) alleles. Don't let this happen!
- There are probably a hundred (or more) genes that contribute to a pigeon's ability to race. The LDHA gene is important, but it is still just one of at least one hundred.
- If you have an outstanding family of birds and they test out as almost all BB, this is actually a very good thing. It means you have the right alleles for many of the other 99 genes. If you add the A allele for LDHA, it will be like throwing gasoline on a fire – BOOM!!!

In 2013 I bred an incredible bird... He was an off the chart freak!

- Earlier this year I started to do some DNA testing for another gene scientists have correlated with race performance in pigeons.
- It is the Dopamine Receptor D4 gene and is commonly called the DRD4 gene.
- It turns out "The Freak" tested CTCT for DRD4 which we will see in a few minutes is super.

- The DRD4 gene codes for the D4 dopamine receptor, which is a protein-coupled receptor found on the surfaces of certain cells of the central nervous system. These receptors are activated by dopamine and are part of an elaborate messaging system within the body used to regulate various neurological processes. DRD4 stands for Dopamine Receptor D4.
- DRD4 has been studied in humans and various mutations of the gene have been linked to a number of neurological and psychiatric conditions such as schizophrenia, certain eating disorders, Parkinson's Disease and even some addictive behaviors.
- Some have tied certain variants of the DRD4 gene to curiosity, restlessness and the urge to explore.

- In 2015, Proskura *et al* published a paper in the journal *Animal Genetics* which studied the association between nucleotide variations at various locations in the DRD4 gene and racing pigeon performance.
- At two of these locations, differences in nucleotide sequences were found to be correlated with race performance for race distances of less than 400 km (249 miles).
- The precise mechanism by which the DRD4 gene influences pigeon racing performance is not understood at this time. Given the wide range of effects found in humans for mutations of this gene, this will most likely not be an easy question to answer.

- Whatever the mechanism, the results of this paper show a correlation and we can use this to our advantage as animal breeders. As was the case with LDHA, additional research is clearly needed.
- The 2015 paper studied race performance for the nine possible genotypes they identified for the DRD4 gene in pigeons:
  - CCCC, CCCT, CCTT, CTCC, CTCT, CTTT, TTCC, TTCT, TTTT
- Not all nine genotypes were found in the test population. Of those that were found, there was a statistically significant difference between the race points earned by the CTCT birds (68.95) verses the CCCC (29.08), CCCT (35.24), CTCC (30.63) and TTCC (29.24) birds.
- It is possible the TTTT, CTTT, TTCT and/or CCTT genotypes are also beneficial, but they are rare enough that none were found in the test group.

### **New Tools – DNA Testing**

Lets see how we might apply this -

- 1) So who do you think I bred "The Freak" to?
  - I poly bred him to:
    - A hen who was AA for LDHA
    - Several sisters, daughters and aunts (his dam was used to produce additional siblings)
- 2) What would I do with a super performing bird that tested BB for LDHA and CCCC (the lowest performing genotype) for DRD4?
  - Stock it! It obviously has the right alleles for many of the other important genes for which we do not yet have DNA tests available.

# **Genes Affecting Racing Ability**

There are several distinct traits which contribute to a bird who wins races. All of these traits are strongly influenced by the environment, but they also have a significant genetic component. The bird has to have the:

- ability to orient itself quickly at the time of release AND maintain the proper orientation on the flight home.
- **ability to fly** at a speed and for a duration that is competitive with the rest of the birds in the race. Many sprint birds, for example, just do not have the tools for competing in a long distance race.
- desire to want to get home quickly (as opposed to just plodding along until it gets there).
- **intelligence to resolve challenges** that inevitably arise at some point during at least some races (*i.e.* strong winds or a storm that breaks up the flock and blows them off course).
- ability to learn from their experiences and their mistakes.
- mindset of a leader as opposed to that of a follower (which is somewhat at odds with their normal gregarious nature).
- willingness to take risks such as starting for home before the pack is ready or to break from a group during the race.

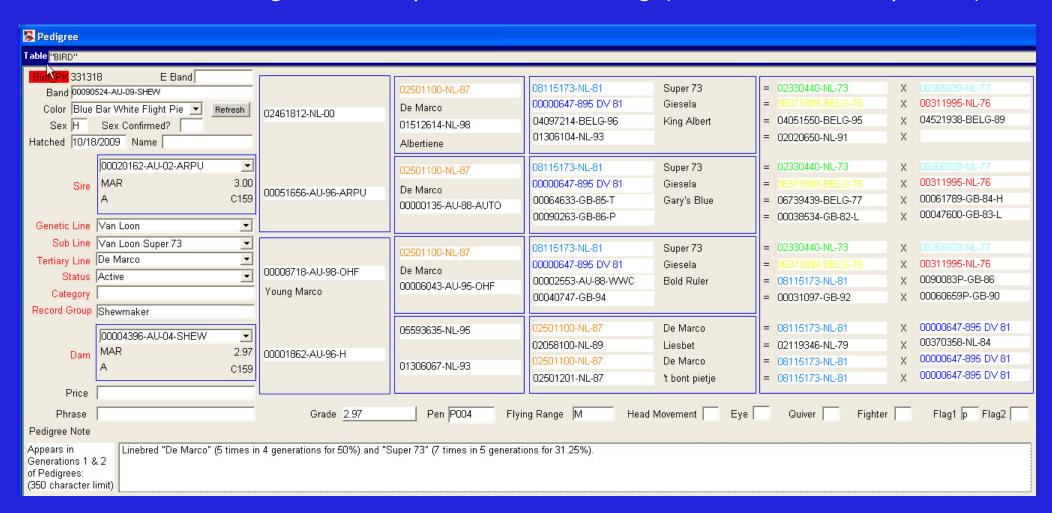

1. Assemble an appropriate gene pool. Don't assume though that you have to go buy new birds. While we all probably need to cull out most of what we have, the American Racing Pigeon Gene Pool is very deep and until you conduct a fair test you really can't say you don't already have the right genes.

#### 2. Roll, roll, roll the dice!!!

- If the genes are in the pool, your job is to assemble them all in one bird.
  - Breed, test and cull until you get it. Then do it again to get another one.
  - Change the matings and do it again.
  - Use linebreeding to try to concentrate the genes of elite birds.

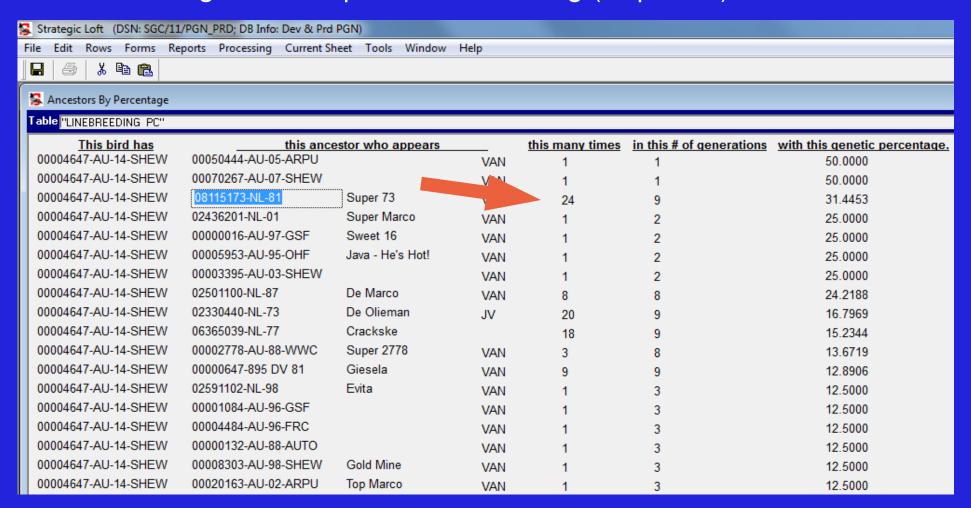

- 2. Roll, roll, roll the dice!!! (continued)
  - · Here is a good example of linebreeding (DeMarco and Super 73):

- 2. Roll, roll, roll the dice!!! (continued)
  - Another good example of linebreeding (Super 73):

- 3. For selection purposes, use only contemporary group test results (Contemporary Groups are groups of birds where the environmental factors for every member of the group are as equal as possible).
  - Loft results for YB and OB races (Combine wins are great for bragging rights and marketing, but useless for genetic selection)
  - Training tosses
  - One Loft Races
  - Your own Contemporary Group Tests

- 4. Perform tough but fair tests. The ideal test is one where only one bird comes in first and is followed over a reasonable period of time with small drops, culminating in all (or at least most) of the birds coming home on the day.
  - The worst possible test is a smash where no one comes home.
  - The second worst test is where the vast majority of the birds come home in the first drop. (It would be an excellent result for YB or OB race or even a training toss but not for a test. A drop of 16 birds for example that score 1-16 in the club or combine speak highly of the handler, but it is really difficult to known whether you had 1 leader and 15 followers or even if you had a flock of 16 and no one bird capable of doing the same on their own.)

- 5.Form your conclusions on patterns, not individual results. In general, don't treat anything as significant until you have three or more noteworthy results.
  - Don't get attached to the pretty ones or the expensive ones or even the ones with a single win. If the results aren't repeatable, they probably aren't statistically significant from a genetic perspective.
  - Two noteworthy results and you may have something.
  - Three noteworthy results and you probably do.
  - Multiple noteworthy results among relatives is the gold standard!

### 6. Shoot to limit selection to top 2% or 1% if possible

- Of course, not every bird you stock will be in the top 2%.
  There are many reasons for exceptions, just don't make
  these exceptions without well thought out and solid
  reasons.
- The message here is not to make it seem impossible, but to emphasize that most of the pigeons we produce and keep are not suitable for moving the flock forward, so be (much) more selective.

- 7. When you get one of the 1% birds, know it is special and do everything you can to breed (and test) as many of its youngsters as you can. Avoid stocking without testing.
  - For 1% cocks:
    - Polygamous breeding
    - Artificial Insemination 300 youngsters a year possible from a single cock
  - For 1% hens:
    - Foster off the eggs to pumper pairs
    - Breed to multiple cocks
  - Repeat the mating that produced the bird and variations of the mating using relatives

- 8.Birds selected for breeding (i.e. the top 2% of racers) have only passed the first test phase. We are really looking for birds that pass Phase 3 Testing:
  - Phase 1 Contemporary Group Testing/Competition.
  - Phase 2 Finding birds that breed the top 2% racers
  - Phase 3 Finding birds that breed birds that breed the top 2% racers.

### 9. Use your tools as would a craftsman, not a hack:

- Inbreeding & linebreeding to selectively narrow the gene pool, then
- Outcrossing when progress has plateaued.
- Use crossbreeding to get an edge when racing (but know this is a disadvantage for breeding).
- Use DNA testing on your top performers to identify their genotypes for LDHA and DRD4.
- Have a goal. Make a plan. Execute the plan. Be
   Observant. Keep an open mind & listen to others, but
   think for yourself. Be honest with yourself. Look to
   improve.

# **Closing Thoughts**

- Remember genes determine the potential. Environment limits how much of that potential is realized. As people get better and better at perfecting the environmental factors (condition, training, fuel, motivation, health and luck) genetics is the one remaining **but unlimited** area in which improvement can still be made.
- This was a crash course and covered way too much information to be absorbed in a few hours. Reread these slides again in a month. They will always be available at www.shewmaker.com.
- I host a discussion group on Facebook called "Pigeons". It is a closed group but any racing pigeon fancier is welcome to join – just send me a Friend Request. We have fanciers from all over the world.

# **Closing Thoughts**

- Most Importantly -
  - Figure out what <u>you</u> are trying to accomplish and focus on that.
  - Remember it is a hobby and it is your hobby. Do it your way.
  - Enjoy the sport! Keep it fun for yourself and the rest of us. We all have enough stress at work.
